

Antibody-drug conjugates: an optimum nobody chose

(a) the measured ratios, and a curve that misses one

(b) more drug per antibody, fewer antibodies

(c) the two orderings disagree

The inputs are two clearance RATIOS from one study (PMID 15501986): a DAR-8 conjugate clears three times faster than DAR-4 and five times faster than DAR-2. The optimum is the output. A single power law fitted to one ratio misses the other by a third, and the acceleration it misses is exactly what makes an interior optimum exist - a smoother curve would have removed the result before it appeared. Panel (c) is the in-vitro-to-in-vivo gap this book argues about elsewhere, with both halves measured in one experiment. Delivered payload is not efficacy, and one conjugate is not all conjugates.
