

Oncolytic virus: the double bind, and the condition that decides it

(a) two arms, opposite directions

(b) the sum, and where its maximum sits

(c) where suppression stops being the answer

Every review of this field states the tension - immunity clears the virus and immunity is the durable mechanism. Stating it settles nothing. What the model adds is a **CONDITION**: below a crossover in priming efficiency the optimum is at full suppression and the clinical intuition is right; above it the same move throws away the durable arm. The crossover's existence is the claim, not its position - priming efficiency is a placeholder in units this model invented. The grey points saturate, where the trade-off has stopped operating and the optimum's location means nothing.
