

What a published target could settle, per arm (4 fitted, 1 directional, 1 unconstrained, 1 partly refuted, 1 inadmissible, 2 with no target)

CAR-T (adoptive transfer)	ADMISSIBLE
Oncolytic virus	ADMISSIBLE
Radiation (DNA channel)	ADMISSIBLE
Synthetic lethality (PARP)	ADMISSIBLE
PDT fluence rate	DIRECTIONAL
Ablation (thermal)	UNCONSTRAINED
Sonodynamic frequency	PARTLY REFUTED
Checkpoint blockade	INADMISSIBLE
ADC bystander effect	NO TARGET
Chemotherapy (cell-cycle)	NO TARGET

ADMISSIBLE means a parameter reproduces a published band, NOT that the arm is validated - none of these feeds a number the manuscript's quantitative chapters report. The three rows that are not green are the informative ones: an UNCONSTRAINED arm has a target so loose it admits almost the whole scanned range, an INADMISSIBLE one has a target that constrains a PRODUCT of factors neither of which is identifiable from it, and an arm with NO TARGET has nothing published to fit at all. Two rows are neither fitted nor failed: a DIRECTIONAL arm has a target that constrains a SIGN and not a value, and the PARTLY REFUTED one is the sharpest row on the page - an independent study CONTRADICTS one of its three directional claims, and it is coloured to be found rather than folded into the greens.
