

Checkpoint blockade: constraining a shape with a ratio the mapping cancels out of

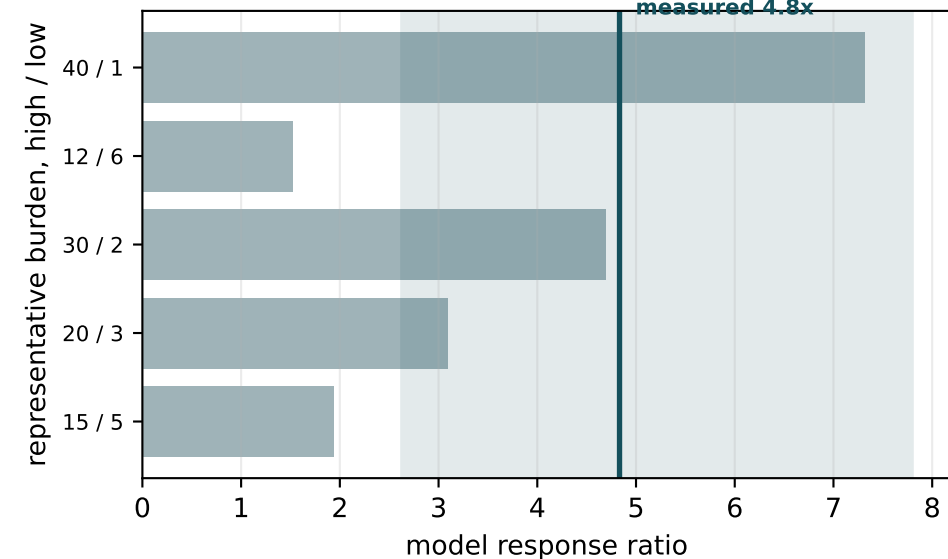

(a) the shape a ratio can test

(b) 31% of the grid survives the ratio

(c) the choice the trial does not make for us

An objective response is a 30% reduction in diameter, not a kill fraction, so no absolute response rate can be compared with this model. A RATIO between two strata of one trial cancels that unknown mapping exactly, and KEYNOTE-158 supplies one stratified by mutational burden - which moves antigenicity and, to first order, not the brake. It constrains a SHAPE and identifies nothing: one ratio is one equation, the brake is untouched, and (c) shows the representative-burden choice moving the model's answer by about as much as the target band is wide.
