

Resistance-mechanism asymmetry: RSL3 (pharmacologic) collapses, SDT (physical) holds (2D model)

2D sim-time. Each panel uses the metric its manuscript section reports, so the figure and prose agree: hypoxia = overall kill (§7.1); stromal = kill among CAF-adjacent boundary cells (§7.3); pH = ferroptosis kills, an immune-free counter (§7.4); immune = ICD kill count (§7.2). Panel (a) is computed without the immune layer (clean O₂-only comparison); panels (b)-(d) share the gradient-O₂ + immune-on baseline the sim runs those mechanisms under (the pH 'neutral' bar reuses the stromal-off run, the only available reference). Confidence tiers differ per panel (titles): the hypoxia leg is the most contested (SDT modeled O₂-independent, an optimistic upper bound, §7.1); the immune 2D ratio over-extrapolates (~4:1 under 3D volumetric dilution). Magnitudes rest on uncalibrated biochemistry; the cross-modality direction is the result, not the numbers.
