

Resistance-mechanism asymmetry: RSL3 (pharmacologic) collapses, SDT (physical) holds (2D model)

2D sim-tme. Hypoxia uses overall kill (normoxic vs hypoxic); stromal and pH use OXYGENATED-RIM kill because in the hypoxic core RSL3 is already floored (~0.1%), so the rim is where CAF/pH suppression of RSL3 is observable; immune uses ICD kill count. Confidence tiers differ per panel (titles): the hypoxia leg is the most contested (SDT modeled O₂-independent, an optimistic upper bound, Section 7.1); the immune 2D ratio over-extrapolates (~4:1 under 3D volumetric dilution). Magnitudes rest on uncalibrated biochemistry; the cross-modality direction is the result, not the numbers.
