

How far each modality reaches into tissue

(a) Kill at the surface and at depth

(b) Retention - and why it cannot be read alone

NOT a ranking. Both panels share one order, sorted by kill at depth, so the UNTREATED arm sits last in both - and in (b) it is the TALLEST bar, which is the point: retention is a ratio, and a ratio of two near-zero numbers is not robustness. Read (a) and (b) together or neither. Attenuation is fixed physics and the two constants are quoted in ONE unit here: PDT 0.31/mm against radiation 0.003/mm, a factor of 103. Printing one per mm and the other per cm made a hundredfold difference read as a tenfold one. Every kill magnitude rests on uncalibrated biochemistry.
