

Adoptive cell therapy: a failure more dose cannot fix

Two tumours with the SAME barriers and the same poor outcome, differing only in antigen density, respond completely differently to the one intervention a clinician reaches for first. That is this arm's only prediction, and it is about an experiment rather than a published number: unlike the checkpoint arm, no ratio is available that cancels the mapping between a remission and a kill, because blood and solid CAR-T are different trials with different endpoints. Nothing here is fitted - the density threshold varies by orders of magnitude with the receptor and the target.
